Amperometric determination of magnesium. A. A. ZANIKO and L. I. Panteleeva. *Trudy Khimicheskoi Anal. Khim., Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 4(7), 135-40 (1953).—The behavior of 8-quinolinol (oxine) was studied. Mg was detd. in salts, and in rocks contg. Ca, Fe, and Al by amperometric titration with oxine soln. The usual app., dropping Hg electrode and satd. calomel reference electrode, was used. Oxine was reduced on the Hg electrode in an ammoniacal buffered soln. of pH 10.0, and gave a limiting current at a potential of 1.86 v. The oxine titrating soln. was prepd. by dissolving the reagent in AcOH and neutralizing the excess acid with NH_4OH . This soln. was standardized with MgCl_2 soln. The MgCl_2 soln. was dild. with the pH 10.0 buffer soln. to 50 ml. At a potential of 1.86 v., oxine soln. was added. The sample was stirred after each addn. Mg was not reduced and only excess reagent increased the current strongly. A small increase at the beginning of titration was caused by the soly. of the ppt. in excess Mg^{++} . In 50 ml., 1.6 mg. Mg could be detd. One ml. of the oxine soln. was equiv. to about 1.5 mg. Mg. Mg could not be quantitatively pptd. in the presence of CaC_2O_4 ppt. whether the excess of oxalate ion added was large or small. Interference of Fe and Al could not be prevented by pptg. Mg in strongly alk. solns. contg. tartrates. Rock samples contg. 3-25 mg. Mg were dissolved in 5 ml. 6N HCl and 3 drops of 3% H_2O_2 . The soln. was warmed, neutralized by 7.5N NH_4OH to methyl orange, and 5% Na_2CO_3 soln. added to ppt. Ca. The soln. was filtered through a small filter and the filter was washed 3 times with water. The filtrate was saved. The ppt. was dissolved in 5 ml. of warm 6N HCl and the filter was washed well with water. The acid soln. and washings were returned to the original beaker and neutralized by NH_4OH to methyl orange. Ca was pptd. again. The ppt. was filtered on the same filter and washed. The filtrates were combined and neutralized to phenolphthalein with NH_4OH . The vol. was not over 50 ml. This soln. was titrated amperometrically with oxine.

POTENTIOMETRIC DETERMINATION OF CHROMIUM,
VANADIUM, AND MOLYBDENUM PRESENT TOGETHER.
A. M. Zanko and M. J. Schljakman (Zavod. Lab., 1934,
3, 777--784).--2 g. of steel are dissolved in 75 c.c. of
10% H_2SO_4 , 7 g. of $(NH_4)_2S_2O_8$ (I) and H_2O to 150 c.c.
are added, excess of (I) is removed by boiling, the
solution is made neutral, poured into boiling 25% aq.
NaOH, diluted to 500 c.c., and filtered. 100 c.c. of
filtrate are conc. to 50 c.c., 1.5 c.c. of 0.1N- $KMnO_4$
and 15 c.c. of 25% H_2SO_4 are added, and the solution is
electro-titrated at 95--100° in a CO_2 atm. with 0.1N-
Cr sulphate (II). The first break in the curve is due to
reduction of $KMnO_4$, the second represents reduction
of Cr^{VI} to Cr^{III} , and of V^{V} to V^{IV} . The titrated solution
is cooled to 70°, a slight excess of $KMnO_4$ is added to
oxidise V^{IV} to V^{V} , and the titration with (II) is
repeated, after which 700 c.c. of conc. HCl and excess of
KCl are added and the titration is continued to the final
break (= reduction of V^{V} to V^{III} , and of Mo^{VI} to Mo^{III}).

% Cr is given by 4.33 (b--c), % V by 6.375c, and % Mo
by 8(d--e), where b is the no. of o.o. of (II) delivered
from the first break to the second, and c and d are the
no. of o.o. of (II) used in the second and third titra-
tions, respectively.

successive potentiometric determination of sulfide,
thiocyanate and chloride ions. A. I. Bursuk and A. M.
Zauko. *Bv. ukrain. vss. Forsch.-Inst. physik. Chem.*
4, 81-8(1934).—To the aq. soln. of the alkali salts, add
5 g. $\text{Ba}(\text{NO}_3)_2$ and 10 ml. of concd. NH_4OH and dil. to
100 ml. Insert an electrode of Ag and titrate potentiometrically
with AgNO_3 against a calomel electrode and
with a bridge of KNO_3 soln. The first break in the titra-
tion gives the S^{2-} content. Then make the soln. acid
with HNO_3 and continue titrating. The next break gives
the CNS^- content and the last the Cl^- . W. T. H.

Use of potassium dichromate for determining the iron content (the total iron and the ferrous iron) of iron ores and silicates. A. M. Zait'ko and A. I. Davydov. *Rev. chim. univ. Forch. 2811. Physik. Chem. 4, 89 198* (1964). Although it is customary to use $KMnO_4$ for the titrations, $K_2Cr_2O_7$ has many advantages. Some difficulty is encountered with the diphenylamine indicator when much $HgCl_2$ is formed after the reduction with $SnCl_2$ and treatment with $HgCl_2$, but the difficulty can be overcome by using as little $SnCl_2$ as possible, adding an excess of $HgCl_2$ at once at a temp. not higher than 25°, waiting 2 min. and then titrating with dichromate. In the detn. of FeO in silicates, the H_2SO_4 used with HF can be replaced by HCl and HF. The results obtained potentiometrically with dichromate are excellent.

PROCESS AND PROPERTIES INDEX

Use of potassium dichromate in the determination of the iron content (total iron content and ferrous oxide) in iron ores and silicates. A. M. ZANKO and A. L. DAVIDOV (Ber. Ukrain. viss. Forsch. physikal. Khim., 1935, 4, 89-96).—Conditions are given for the titration of Fe⁺⁺ with K₂Cr₂O₇ potentiometrically, and using the NHPb₂ indicator. Fe⁺⁺ is reduced by SnCl₂, and the excess removed by HgCl₂. The amount of HgCl₂ formed must be small, otherwise the NHPb₂ end-point is affected. Insol. silicates are treated with HCl + HF and the titration is carried out as above. The val. of the equivalence e.m.f. is affected by the presence of F⁻ but is independent of Fe⁺⁺⁺.

PROCESSES AND PROPERTIES

Determination of iron, titanium and aluminum in a mixture with the aid of 8-hydroxyquinoline. A. M. Zasl'ko and O. A. Butenko. *Zashchita Lab.* 5, 415-18 (1936).—The improvement of the method of Tainberg (C. A. 29, 70⁴) and its modification by Zhukovskaya and Balyuk (C. A. 29, 2876⁹) is based chiefly on the use of accurate AcOH acidity and a definite balance between tartaric acid and NH_4 oxalate of soln., making a complete sepn. of Ti and Al with 8-hydroxy-quinoline-AcOH (I) possible. The method is shown in a prepd. soln. of Fe_2O_3 , Al_2O_3 and TiO_2 . To 100 cc. of the soln. add 3 g. NH_4OAc and 1 g. tartaric acid, neutralize with NH_4OH and introduce 20 cc. of 80% AcOH and a slight excess of 2% I. Bring the soln. nearly to boiling, digest on a water bath, filter off Fe oxine through a glass filter No. 4, wash the ppt. with 1% AcOH and water, dry it at 110° and weigh. Evap. the filtrate to 150 cc., add 4 g. NH_4 oxalate, neutralize the soln. with NH_4OH to litmus, add 3-5 drops of AcOH, heat to 60°, ppt. with I, boil 10 min., filter off Ti oxine, wash with hot water, dry at 110° and weigh. Dil. the filtrate to 500 cc., withdraw 100 cc., add an excess of NH_4OH and I, and proceed with the sepn. of Al oxine as above. The oxines can be dissolved and titrated by the Berg method, or preferably by the potentiometric method of Atanasiu and Velculescu (C. A. 28, 433⁹) C. H.

Analysis of copper-nickel-aluminum alloy with the help of organic reagents. A. M. Zankov and A. Ya. Bursuk. *Rev. Inst. physik. Chem., Acad. Sci. U.S.S.R.* 6, 245-6 (1938). --Dissolve 0.5 g. sample in 15 cc. HNO₃ (1:1), evap. to a syrupy state, wet with H₂SO₄, heat to fumes of H₂SO₄, cool, dissolve residue in hot water, neutralize with a few drops of NH₃, add 10 cc. of 2 N H₂SO₄ and electrolyze to get Cu. Heat the soln. to boiling, add 3 g. tartaric acid, 15-20 cc. of 1% alc. soln. of dimethylglyoxime, and enough NH₃ to make alk. Filter, wash the ppt. with hot water, dry at 110-120° and weigh. Dil. the filtrate to 300 cc., withdraw 100 cc., and add to it 2 g. tartaric acid, 5 g. NH₄Cl, and enough NH₃ to color phenolphthalein. Then, while shaking, add in drops 20 cc. of 2% acetic soln. of 8-hydroxyquinoline. Heat for one-half hr., filter, wash ppt. with hot water until free from Cl ions, dry, ignite at 1000° and weigh as Al₂O₃. B. Z. Kamich

***Electrolytic Delineating of Tinplate Scrap, and a Micro-Method for Determining its Lead Content.** A. M. Zanko and N. S. Krugovoi (*Ber. Ind. physikal. Chem., Metall. Wiss. Techn. S.S.R.*, 1930, 6, 247-265; *C. Abc.*, 1937, 31, 6075). [In Russian, with German summary.] The tin layer was first removed by anodic oxidation in sodium hydroxide solution. The stannate solution was then electrolyzed to eliminate lead as PbO_2 . The PbO_2 was then collected, and determined iodometrically or colorimetrically. - S. G.

Determination of iron, titanium and aluminum in a mixture with dibromohydroxyquinoline. A. M. Zankov and A. Ya. Bursuk. *J. Applied Chem. (U.S.S.R.)* 9, No. 8 (in English 898) (1936).—The Berg method (*C. A.* 24, 4479; 25, 3263) was applied to the detn. of Fe, Ti and Al in the presence of one another. The detn. depends on the sepn. of Fe with 8-hydroxyquinoline (1), and pptn. of Ti and Al at different acidities with dibromohydroxyquinoline formed directly in the filtrate by bromination of 1 (cf. Atanasiu and Vekulescu, *C. A.* 28, 4367). To a soln. contg. 10 mg. of Fe, Ti and Al add 1 g. tartaric acid and 3 g. Me_2CO , then neutralize with NH_4OH , and introduce 10 cc. of concd. AcOH and 6 cc. of 2% 1 in AcOH . Digest the soln. on a water bath for 30 min., filter off the Fe oxine through a Schott filter No. 4, wash and dry it at 110° to a const. wt. Dil. the filtrate to 150 cc., withdraw 50 cc., introduce 20 cc. of 2 N HCl , heat the soln. to 50° , add 9 cc. of 0.2 N $\text{KBr} + \text{KBrO}_3$, digest on a water bath for 2-3 min., filter off the Ti dibromoxine, wash it with 200 cc. of 0.04 N HCl contg. 10% Me_2CO , and dry at 185° to a const. wt. To det. Al, conc. the filtrate (if necessary), introduce 3 g. NH_4NO_3 and 15 cc. Me_2CO , then neutralize with NH_4OH to a slightly alk. reaction, heat the soln. to incipient boiling, and digest it on a water bath for 10 min. Filter the Al dibromoxine through a Schott filter, wash it first with a warm 10% Me_2CO soln. contg. 1.5% NH_4OAc and little NH_4OH and then with H_2O , and dry at 190° to a const. wt.

Determination of copper in cast iron and steels by precipitating with quinaldic acid. A. M. Zan'ko and G. A. Butenko. *Zarodkova Lab.* 6, 515-8 (1957).—A modified Ray and Rose method (C. A. 25, 1625) for the sepn. of Cu from Fe is described. The method was used in detg. Cu in cast Fe and steels with an accuracy to 0.04%. Dissolve a 1-g. sample in 15-20 cc. of 50% HCl with addn. of 2-3 cc. HNO₃, evap. to dryness, dil. and filter as usual. Ignite the SiO₂, evap. with H₂SO₄ and HF to fuming, dissolve the residuc in H₂O, filter and unite the 2 filtrates. Introduce into the filtrate 0 g. tartaric acid, neutralize with NH₄OH to nitrazine-yellow paper by the spot method (cf. Vasserman, C. A. 29, 1027), add 15 cc. of 4 N H₂SO₄, boil and introduce dropwise an excess of the Na salt of α-quinaldic acid. Next day filter through a porous glass funnel, dry at 125° and weigh as Cu(C₁₀H₆NH₂)₂·H₂O. The decompn. of the SiO₂ with H₂SO₄ and HF can be omitted with completely sol. steels. Chas. Blanc.

Determination of copper in cast iron and steels by means of 5,7-dibromo-8-hydroxyquinoline. A. M. Zep'ko and A. Ya. Bursuk. *Zavodskaya Lab.* 6, 6758 (1977). The adaptation of Berg's method (C. A. 26,

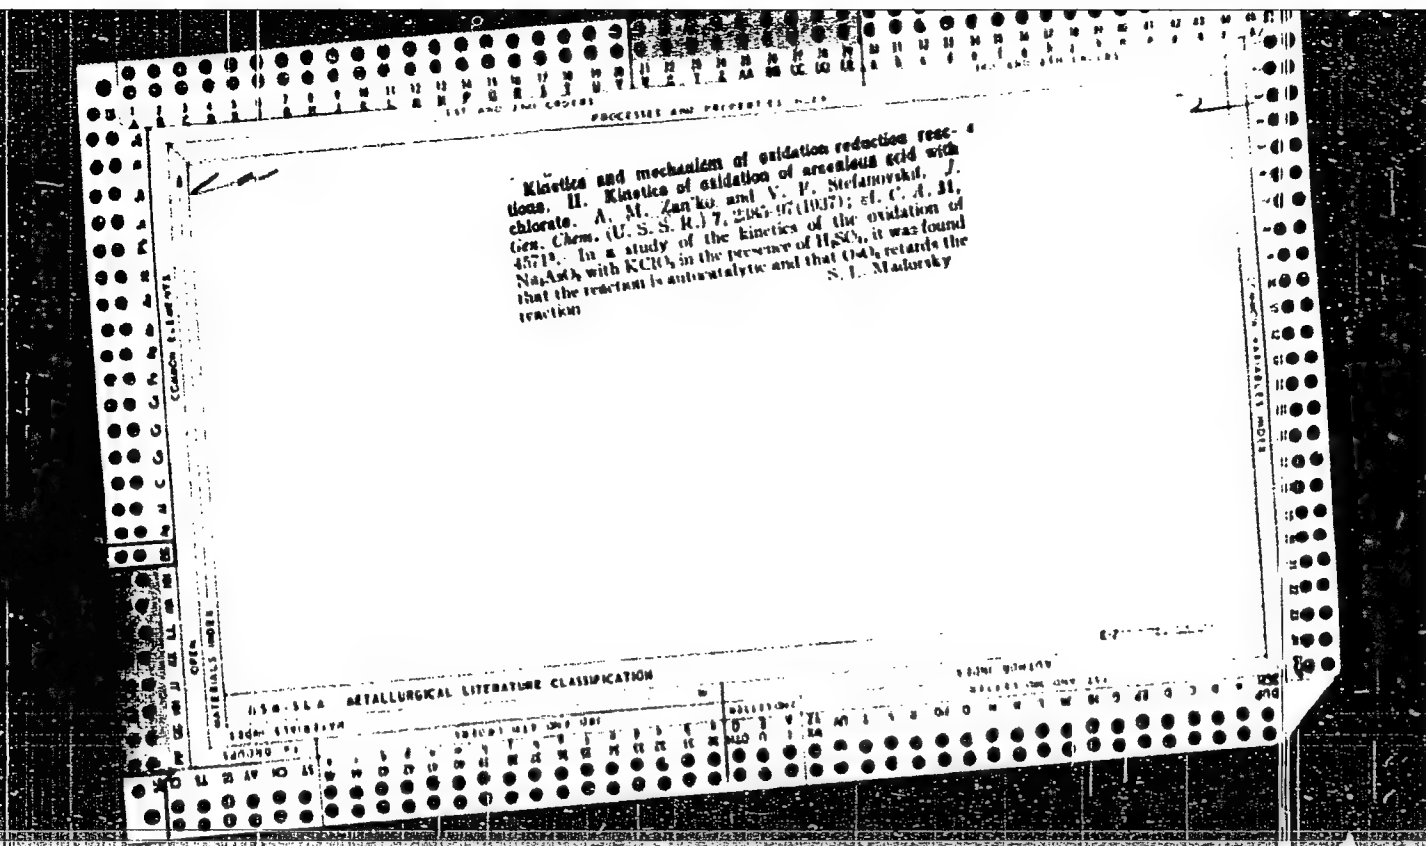

2135) to the detn. of Cu in cast Fe and steels is made possible by the use of a definite excess of $(\text{NH}_4)_2\text{C}_2\text{O}_4$ and optimum concn. The detn. is accurate to 0.004-0.04% for 0.07-2% Cu content. Decomp. a 0.5-1 g. sample in 15 cc. of 60% HCl, oxidize with 2 cc. HNO_3 , evap. the soln. to dryness and heat the residue in a drying oven at 20-30°. Dissolve the residue in HCl and water and filter from SiO_2 . Decomp. the SiO_2 with H_2SO_4 and HF as usual, dissolve the residue in H_2O , filter and unite the 2 filtrates. Dil. the soln. to 100 cc., introduce 15 g. $(\text{NH}_4)_2\text{C}_2\text{O}_4$, heat and neutralize with NH_4OH to nitrazine-yellow paper by the spot test (cf. Vasserman, C. A. 29, 1027). Treat the soln. with 15-20 cc. of N HCl and 10-15 cc. acetone, then heat it to 60° and introduce dropwise, with shaking, 0.5% 5,7-dibromo-8-hydroxyquinoline in acetone in excess (not exceeding 0.05-0.08 g.). After digesting on a water bath for 2-3 min., filter and wash the ppt. with 100 cc. H_2O , contg. 0.5 g. $(\text{NH}_4)_2\text{C}_2\text{O}_4$, 4 cc. of 0.1 N HCl and 10 cc. acetone, and then 10-12 times with hot H_2O . Dry the ppt. in a Goussier crucible in an oven at 100° and then at 180° toward the end, then weigh and det. as $\text{Cu}(\text{C}_8\text{H}_6\text{Br}_2\text{NO})_2$. Chas. Blanc

The mechanism of oxidation-reduction reactions 1. Qualitative relations. A. M. Zait'ko and V. P. Stefanyuk. *J. Gen. Chem.* (U. S. S. R.) 7, 100-101 (1937). Partially reversible oxidation-reduction systems show an anomalous rise in the potential when the oxidizer is titrated with the reducer. The effect of polarization of a Pt cathode is stronger in these systems when they are less reversible. In more reversible systems, the original potential is reached sooner and more fully. The effect of polarization of a Pt anode is not due to passivation. The polarization of a Pt anode in the reduction of $K_2Cr_2O_7$ by $FeSO_4$, anomaly is shown in the reduction of $K_2Cr_2O_7$ by $FeSO_4$, $K_4Fe(CN)_6$, K_2AsO_4 , $NaCl$, Na_2SO_4 and $CrSO_4$, but not by KI , $NaNO_3$, $Hg(NO_3)_2$ or mixts. of KI with K_2AsO_4 or $FeSO_4$. When the anomaly occurs, it is smaller (except for $CrSO_4$) when the potential difference between oxidizer and reducer is greater. With increasing acidity of the soln. the original potential of the system increases, but the size of the anomaly decreases. The anomaly is greater in HCl than in H_2SO_4 solns., and it diminishes with increasing temp. All these facts are best explained by the assumption of the formation of an intermediate compd. with a greater oxidizing power than that of the original substance. H. M. Leicester

The interferometer in the analysis of dilute solutions of strong electrolytes. A. M. Zan'ko and I. L. Kukhtevich. *Izudy Dnepropetrovsk. Khim.-Tekhn.-I. Inst.*, 1938, 33 (6), *Khim. Refrat. Zhur.* 2, No. 2, 70 (1939).—The possibility of using the interferometer for detg. the concn. of substances in aq. solns. is shown by a study of solns. of HCl, NaOH and Na₂CO₃, which were 0.001-0.100 N. The method can be used only for measurements of pure substances in soln. but is then more accurate than the usual methods of analysis. Details for carrying out the work are given.
W. R. Henn

1A

POTENTIOMETRIC DETERMINATION OF SMALL QUANTITIES OF MANGANESE. A. M. Avrunina and A. M. Zan'ko, *Zashch. Khim. 7*, 1238-42 (1948).—In Park's method (*C. A.*, 30, 479) for the potentiometric detn. of Mn by oxidation with NaBiO_3 , the MnO_2 is reduced with excess NaHSO_3 and the excess titrated with KMnO_4 in the presence of a little CeO_2 . Equally good results can be obtained by direct titration of the MnO_2 with the NaHSO_3 soln. Since a large excess of Fe^{2+} does not disturb the detn., the method can be used in the analysis of steels. Oxidation of Mn by the persulfate method gives high values.

Determination of copper in cast iron and in steel by means of dibromohydroxyquinoline. A. M. Zan'ko and A. Ya. Bursuk. *Izv. Inst. physik. Khim., Akad. Nauk. Ukr. S. S. R.* 9, 93-97 (1934); *Khim. Referat. Zhur.* 1, No. 40, 92-3; cf. *C. A.* 31, 8421f. The method for the detn. of small amts. of Cu in presence of large amts. of Fe consists in the introduction of NH₄ oxalate in twice the theoretical amt. for the formation of the oxalate complex. Fe does not ppt. from acidic solns. of dibromohydroxyquinoline, while Cu is pptd. completely. By means of this method 0.07-1% (and slightly higher amts.) of Cu in steel and in cast iron can be detd. W. R. Henn

ASH-55.4 METALLURGICAL LITERATURE CLASSIFICATION

Determination of copper in cast iron and in steel with quinaldic acid. A. M. Zam'ko and G. O. Hutenko. *Rev. Inst. Phys. Chem. Akad. Wiss. Ukr. S. S. R.* 9, 99-107 (1938); *Khim. Referat. Zhur.* 2, No. 3, 73-4 (1939).
The method is based on the relative instability of the tartaric complex of Cu at a definite acidity of the soln. and on the fact that the quinaldinate of Cu is less sol. than are the corresponding compds. of the other elements in steel and cast iron. For the analysis dissolve 1 g. of the metal in 15-20 cc. of 6 N HCl, acidify with 2-3 cc. of concd. HNO₃, boil for some time, evap. the soln. to dryness in a porcelain dish and sep. the SiO₂ by the usual method. Filter off the residue, roast it, treat it in a Pt crucible with HF + H₂SO₄ (until white fumes appear), ext. with water and add the soln. to the original filtrate. Add to the mixt. 6 g. of tartaric acid, neutralize to nitrazine yellow paper with NH₄OH, add 15 cc. of 4 N H₂SO₄, heat to boiling and ppt. (by stirring) with an excess of a 2% soln. of Na quinaldinate. Let the mixt. stand (total vol. 100-120 cc.) for 18 hrs., filter through a glass crucible No. 3 or 4, wash the residue with hot water, dry at 125° and weigh. One g. of ppt. = 0.1494 g. of Cu. If the amt. of Cu in the sample is less than 0.05-0.001% take twice as much sample and twice the quantities of tartaric acid and of 4 N H₂SO₄. The Cu values obtained are accurate within 0.02% of the wt. of sample.

Polarographic and photocolometric determination of oxygen in water. A. M. Zait'ko, P. A. Manusova and A. D. Nikitin. *Zashchita* Lab. B, 937-40(1939).-- A comparative study was made of the polarographic and colorimetric (with NH_4Cu complex) methods for detg. O in water. Both methods give comparable results to 1 ml. when the O content is 1 to 0.1 mg. the use of the polarographic method involves various difficulties including the effect of temp., contact of the sample with the O of the air, and small height of the O waves. A colorimetric method based on the reaction of o-tolidine on Cu can be used if the O content is below 1 mg./l. (down to 0.01 mg./l.). In this method a part of the NH_4Cl soln. of Cu is evapd. until NH_4Cl begins to crystallize, the soln. is cooled, the crystals dissolved, 1-2 ml. of 0.3% gelatin and 0.5-1 ml. of 1% toluene are added, the soln. is dild. with a satd. soln. of NH_4Cl , and the Cu is detd. colorimetrically.

M *11*

Polarographic Determination of Aluminium in Magnesium Alloys. B. A. Heller and A. M. Zan'ko. (Zavod. Lab. (Works' Lab.), 1939, 8, 1030-1032; C. Aba., 1940, 34, 1583).—[In Russian.] Dissolve a 0.2-0.5-grm. sample in a small excess of 2N-HCl, cool, add a solution of bromophenol blue, neutralize carefully at first with milk of lime until the yellow colour begins to change to yellow-green, and then neutralize completely with a saturated solution of $\text{Ca}(\text{OH})_2$ to the bright green colour of the reference solution (buffer solution with p_H 3.3, coloured with bromophenol blue). When artificial lighting is used the end of the reaction is determined by the change of the yellow-green to a brown-green colour. The solution is then diluted to 100 ml., poured into an electrolyzer, and polarographed, starting with 1-4 v. The procedure lasts 20 minutes and is applicable for Mg alloys containing up to 19% Al. The errors ranged up to 6-8%.

ASH-51A METALLURGICAL LITERATURE CLASSIFICATION

Use of 8-Hydroxyquinoline in Polarographic Titrations. A. M. Zan'ko
(Dok. Akad. Nauk U.S.S.R., 1940, 27-31, 32-33; *Chem. Zvest.*, 1942, 113;
(11), 1006; *C. Abstr.*, 1943, 37, 5021).—(In Russian.) The optimum conditions
for the polarographic determination of Zn, Cu, and Al with oxine in a buffered
in Zn determination, the oxine precipitated is formed preferably in a buffered
in Zn determination as recommended by Berg and the titration carried out as
directed by Abrecht. A N-cathode electrode is used for reference. The
dissolved hydrogen is not removed and its diffusion stream is compensated.
The accuracy of the titration is improved by making the volume of solution
small at the start and with constant increase in the concentration of the
reagent solution. Cu is determined similarly. Mg, on the other hand, is
best precipitated in aq. NH_4OH solution containing NH_4Cl . The Al can be
determined either in ammoniacal or in CH_3COOH solutions. The results
obtained in test analyses are tabulated.

Polarographic determination of zinc in magnesium alloys. B. A. Heller and A. M. Zaitko. *Zhurnal Fiz. Khim.* 1940; cf. C. A. 34, 1581. The method is based on the elimination of the O_2 wave with Na_2SO_3 . Dissolve 0.25 g. of the Mg alloy in a min. amt. of HCl (1.2), add 6-7 g. NH_4Cl , 2.5 ml. of 20% Na_2SO_3 soln. and 18-20 ml. of NH_4OH , cool if necessary, dil. to 50 ml. and polarograph. The detn. requires 15-20 min. The relative error is up to 3%.

Polarographic determination of titanium. A. M. ZAN'KO, B. A. GALLER, AND A. D. NIKITIN. *Zashchita Tsv. i* [9] 976-79 (1940); *Khim. Referat. Zhur.*, 4 [3] 52 (1941).—Small amounts (0.1 to 0.5%) of Ti can be determined polarographically in the presence of large quantities of Fe and Al (50 to 80%). The determination should be conducted at an acidity not less than 0.05 N in the presence of tartaric or citric acid. Fe^{+++} and O interfere. The former is changed to the divalent form by shaking it with the Hg of the anode for 5 to 10 min. Simultaneously, the O is completely removed from the solution by reaction with the reduced Fe. For the analysis of kaolin, 0.3 gm. is treated with $H_2SO_4 + HF$, and the insoluble residue is fused with potassium pyrosulfate. The fusion is dissolved in the first filtrate, a little iron sulfate is added to it, and the volume is made to 50 cc. Ten milliliters are taken into the electrolyser, N is passed for 5 min., 0.5 gm. of tartaric acid is added, and the solution is analysed. An alternate method consists in dissolving the sample in HCl, igniting the insoluble residue, treating it with HF, and fusing with potassium pyrosulfate. The fusion is dissolved in the first filtrate, and the analysis is finished as before. The results obtained by this method agree with those obtained gravimetrically and colorimetrically.

| <p><i>ca</i></p> <p>An application of nonaqueous solutions in polarography. A. M. Zait'ko and F. A. Mannova. <i>J. Gen. Chem.</i> (U.S.S.R.) 10, 1171 (1940).— The following solns. were analyzed polarographically: 0.1 N $\text{Pb}(\text{NO}_3)_2$ satd. soln. CdSO_4, SnCl_2 and ZnCl_2 in HCOONH_4 (dielec. const. 84 eq. compared with that of water 81.7); 0.1 0.005 N salts of Cd^{++}, Al^{+++}, Mn^{++}, Ba^{++} and Ni in EtOH and MeOH (17.3 and 33, resp.) in the presence of 0.1 N CaCl_2, N NH_4Cl or 2 N MgCl_2; 0.1 N salts of Cd^{++}, Pb^{++}, Mn^{++}, Al^{+++} and Zn^{++} in glycerol, in the presence of 2 N MgCl_2, and N AlBr_3 in C_2H_5 in the presence of KBr. All solvents were mixed with various apts. of water. The potential of semi-wave was practically unchanged in the presence of indifferent electrolytes as compared with that of an aq. soln. The height of the wave of diffusion current as a rule was considerably smaller in the nonaq. solns. than in aq. solns., at the same concn. of the substance undergoing a reduction. A direct proportionality was observed between the height of the polarographic wave and the concn. of ion that was reduced, provided chem. interaction between that ion and solvent was absent. Polarograms of all the above solns. were obtained with the exception of AlBr_3 in C_2H_5, which, because of high concn. of AlBr_3 and low concn. of KBr, cannot be measured. A. A. Podgorny</p> | | | | | |

Polarographic Analysis of Magnesium Alloys. B. A. Heller and A. M. Zankov. *Izv. Pishchepusky Inst. fizik. Chem., Akad. Wiss. U.S.S.R.*, 1940, 2, 169-176 (in Russian, 176; in German, 176); C. Abt., 1941, 33, 2441).—*Cf. Met. Abs.*, this vol., p. 40. Hydrolysis of Al⁺⁺⁺ at a p_H of 3-4 causes error in the polarographic determination of Al and also in the calibration curve below the start of the co-ordinates. The following method is suggested for the rapid determination of up to 10% Al in Mg alloys. Dissolve 0.2-0.5 gm. sample in 2N-HCl, cool, add bromophenol blue, neutralize gradually with milk of lime to a yellow-green colour, and then with Ca(OH)₂ to a bright green of the comparator—a buffer solution of p_H 3.3 containing bromophenol blue. Dilute the solution to 100 ml. and take the polarogram, starting at 1-4 v. The error is 5-8%.

Calculation method of polarographic analysis. A. M. Zan'ko, B. A. Geller and F. A. Mannaeva. *Zavodskaya Lab.* 10, 488-01 (1941).—On the basis of the detn. of Cd⁺⁺ in various electrolytes it is shown that it is possible to use the calcn. method of polarographic analysis by using the Ilkovic equation and empirically detd. effective coeffs. of diffusion. The calcn. analysis is possible only when there is a direct proportionality between I_d and C where $I_d = K' C m^{2/3} t^{1/2}$ and C is concn. in mols. per ml., I_d is the diffusion current in amps., m is the amt. of Hg flowing out of the capillary in g./sec., and t is the time of formation of one drop in seconds.

Utilization of Medial Interference in the Mercury Electrode. A. M. Zankov and P. A. Manasova. *Zashchita Lab.* 10, 645 8(1941).—In analysis of alloys of Fe with Cr it is not necessary to sep. these components. It is possible to study the components of a soln. by oxidizing the ions of metals or the molts. of org. substances. Expts. were carried out with a mist. of Cr^{3+} and Cr^{6+} . Bubble pure N_2 through a H_2SO_4 soln. of Cr^{3+} , for 3 hrs., and Cr^{6+} with the mist. with N_2 and det. the polarogram. At 11° 0.001 N, 2 waves were observed on the polarogram: an anodic wave corresponding to $\text{Cr}^{3+} \rightarrow \text{Cr}^{6+}$ (0.84 v.) and cathodic wave corresponding to $\text{Cr}^{6+} \rightarrow \text{Cr}^{3+}$ (0.97 v.) with respect to the satd. calomel electrode. Attempts to combine the waves by adding tartaric acid or $(\text{COOH})_2$ were unsuccessful; hence the oxidation and reduction potentials are irreversible. In the presence of Fe^{3+} (even as much as $\text{Cr:Fe} = 1:1000$) the waves of Cr remained sufficiently clear and the proportionality between the height of the wave and the concn. remained unchanged. The salts of Cr^{6+} were reduced to Cr^{3+} by means of liquid Zn amalgam. Reproducible results are obtained. The calibration curve obtained showed a direct proportionality between the height of the wave and the concn. of the ion. To analyze standard samples of simple Cr salts, dissolve the sample (0.1–0.5 g.) in 20 ml. of H_2SO_4 (1:4) or HCl (1:1) with heating, add a pinch of $\text{K}_2\text{S}_2\text{O}_8$, boil to decomp. excess $\text{K}_2\text{S}_2\text{O}_8$, cool, transfer the soln. to a 50-ml. measuring flask, and dil. with water to the mark. Reduce an aliquot part of the soln. and exam. in the polarograph. Twelve references.

Magnitude of the diffusion coefficient in the equation of Il'vichev. A. M. Zakh'ko, H. A. Geller and P. A. Manakov. *J. Phys. Chem.* (U. S. S. R.) 19, 797 MKI(1945).—The Il'vichev (*C. A. 32, 8082*) coeffs. of diffusion $D = [(14)/(0.627 \sqrt{mCw}/t)]^2$ cm.²/sec. (m = mass of Hg flowing from capillary per sec., t = time, C = concn.) of Cd⁺⁺ and Tl⁺ ions in 0.1 N solns. of various electrolytes at 25° were detd. by the potentiographic, the capillary-mercury-electrode and the Koltzsch-Laitinen methods. The values of $D \times 10^5$ cm.²/sec. obtained for Cd and Tl were, resp.: in HCl, 1.08, 2.33; MgCl₂, 1.03, 2.17; Al₂(SO₄)₃, 0.90, 0.92; K₂SO₄, 0.95, 2.18; Al₂(SO₄)₃, 0.89, 1.60; H₂SO₄, 0.87, 9.12; AgNO₃, —, 1.94. The mean value of $\mu \times 10^5$ sec. is 49.0 = 0.8. The Nernst equation, $D = URT/nF$, using the ionic mobilities at infinite diln. is not applicable.

| 5 | <p>Polarographic Determination of Titanium in Ferrous Metals. A. M. Zayko, H. A. Geller, and A. D. Nikitin. (Zavodskaya Laboratoriya, 1947, vol. 13, pp. 299-300; Chemical Abstracts, 1948, vol. 42, May 20, col. 3291). The method is suitable for steels and cast irons containing 0-1% of titanium and over; the analysis requires 20-25 min and the results are within 5% of the truth. Dissolve 0.2 g of steel or cast iron in 5-5.5 ml of 9N H₂SO₄, add 1 ml. of 7.5N HNO₃ and heat to H₂SO₄ fumes. Dissolve the residue in water, add 3-5 g of NaK tartrate, and dilute with water to 25 ml. Transfer part of the solution into an electrolyser, add one drop of KSCN solution, and reduce the Fe³⁺ with aluminium dust by heating to disappearance of red coloration. Cool the solution, blowing nitrogen through it for 5-7 min. and then make the polarographic test. Satisfactory results were obtained with cast irons containing about 1% of titanium and also standard steel containing 0.4% of titanium and 17% of chromium (chromium did not interfere). The calculation of the Il'kovich equation is described.</p> |

Orig Pub: Lozarstvo i vinarstvo, 1957, 6, No 1, 4-7.

Abstract: In 1951 experimental plantings were conducted of scion-rooted vineyards on sandy soils on an area of 60 ha in a series of Bulgarian rayons. Sand content in the soil was 69-81% to a depth of 140 cm. Phylloxera does not develop in these conditions. The best harvest was gathered in the third year from the "Mavrud" variety (11 t/ha) and from the "Pamid" variety in the fourth year (13 t/ha).

Title : Experiments with Short and Long Pruning of Some Wine Grape Varieties.

Orig Pub : Lozarstvo i vinarstvo, 1957, 6, No 3, 4-19

Abstract : As the result of experiments conducted in 1952-1953 in the vineyards of labor cooperatives, the authors have reached the conclusion that the load of 8-10 eyes per plant, presently used on the establishments in Bulgaria, is insufficient. With the present agricultural technique it can be increased on the Dimyat, Vinenka, Red Muscat and Mavrud varieties to 24 eyes, and on the Pamid variety - to 32 eyes per plant both with short and long pruning. Further increase in the fruit bearing load is feasible with the improvement of the agricultural

Title : Time of pruning grape vines

Periodical : Dokl. AN SSSR, 96, Ed. 2, 395 - 398, May 1954

Abstract : Early-fall and late-spring pruning of grape vines results in greater loss of plastic substances which leads to the weakening of the bush and reduction of yield. The most proper time for pruning is the period of rest. The loss of carbohydrates is then very small and the yield is maximum. The period of rest is considered the time when the plant does not vegetate and the temperature is still above freezing, (late-fall or early-spring). Nine references. Tables.

 : The Nature of the Black Mulberry Tree

ORIG. PUB. : Roczn. Sek. dendrol. Polsk. towarz. bot., 1956, 11,
 397-402

ABSTRACT : Because of the variability (from white to almost black)
 in color of fruit, white mulberry is often confused with
 black. The latter originates in Persia, Syria and
 Palestine, where it has been grown for a long time. In
 the middle ages it appeared in Europe considerably
 earlier than the white mulberry. The propagation of
 the white mulberry stopped the cultivation of the black,
 and at the present time it is found, as a rule, in the
 wild state. The black mulberry differs from the white in
 its lesser height, more compact crown, slower growth and
 in a series of morphological characteristics (described).
 The fruits of the black mulberry contain less sugar than

The constitution of 2,3-perinaphthoquinoline and its derivatives. Jan Morawey and Wanda Zankowska-Jasinska (Univ. Kraków, Poland). *Kwart. Chem.* 32, 229-33 (1978) (German summary); cf. *C.A.* 50, 342a. -- Condensation of acenaphthone (I) with (m-MeC₆H₄NH)₂CS gave 3-(m-toluidino)-7-methyl-2,2-perinaphthoquinoline (II), m. 216°. In order to confirm the position 7 of the Me group, I was condensed with 2-chloro-3-methylaniline at 180° or with 2,2'-dichloro-3,3'-dimethylthiourea, m. 184-5°. In all the reactions bisaczone, m. 260°, and decacyclene (III), m. 387°, were formed. The structure of II was proved by the Niementowski method [*Ber.* 27, 1394(1894)]. I reacted with anthranilic acid at 110-210° giving III and 4-hydroxy-(2,3-perinaphthoquinoline) (IV), m. 420°. Identical with the product of hydrolysis of 4-quinico deriv. of IV (Bz deriv., m. 241°). Condensation of I with 2-amino-3-methylbenzoic acid yielded under similar conditions the 7-Me deriv. of IV, m. 420° (Bz deriv., m. 230-1°), which is identical with the hydrolysis product of II. The results confirm the previous view on the properties of I in reactions with diaryl deriva. of thiourea.

Synthesis of derivatives of 2,3-peri-naphthalenequinoline.
Jan Mucarsy and Wanda Zaskawska (Univ. Jagińska,
Krakow, Poland). *Russkii Khim.* 18, 162-4 (1951).—
Condensation of 1-acenaphthone (I) with diaryl deriva-
tives of thiourea produces derivs. of 2,3-peri-naphthalenequinoline
substituted in the 4-position (12-substituted acenaph-
tho[1,2-b]quinolines) (II). Alk. KOH transforms them to
the corresponding 4-HO compds (II, R = OH). CA.

(NHPh), and I yield at 120-60° the 4-anilino derivs. (III).
(II, R = PhNH, R' = H), light-green plates, m. 264°.
(HCl salt, m. 267°; picrate, m. 281°); 4 hrs. alc. KOH hy-
drolysis at 100° and 40 atm. transforms II to the HO analog,
decomp. 270° (from quinoline). (p-MeC₆H₄NH)₂CS
and I condense to 2,3-peri-naphthalene-4-(p-toluidino)-6-
methoxyquinoline (II, R = p-MeC₆H₄NH, R' = Me), yellow
needles from C₆H₆, m. 257.5° (picrate, decomp. 281°), hy-
drolyzed to the 4-HO analog, light yellow needles,
m. 432°. (p-MeOC₆H₄NH)₂CS and (p-ROC₆H₄NH)₂CS
react similarly, and, after distn. of the unreacted starting
materials, yield 4-(p-anilidino)-6-methoxyquinoline, m.
211.5° (from R₂OH) (picrate, m. 269°), and 4-(p-phenetidino)-
6-ethoxyquinoline, m. 109-90° (from EtOH) (picrate, m.
283°); both hydrolyzed to 2,3-peri-naphthalene-4,6-di-
hydroxyquinoline, m. 350° (decomp.) (from PhNO₂).

Moscow J. Zankowska-Jasinska W. The Synthesis of 2,3-Perinaphthylenequinoline.

Synteza 2,3-perinaphtylenukwinoliny". Roczniki Chemii (PAN). No. 3, 1964, pp. 432-443.

From the previously obtained compound having the structure of 6-hydroxy-2,3-perinaphthylenequinoline a 4-chloroderivative (yellowish needles, m.p. = 183°) was obtained by the action of phosphorus pentachloride, and from this, by way of reduction, free base viz. 2,3-perinaphthylenequinoline (yellowish plates, m.p. = 185°). Also synthesis was carried out of the new compound having the basic molecular system of 2,3-perinaphthylenequinoline. Condensing acetophenone with thio-carb-m-toluidide, a compound was obtained which corresponded in composition to 5- or 7-methyl-4-m-toluidine-2,3-perinaphthylenequinoline (small yellowish plates, m.p. = 214°). Heating this compound with an alcoholic solution of potassium hydroxide, the remaining toluidine in position 4 was separated and substituted by the hydroxyl group (yellow rods, m.p. = 220°).

TITLE: The possibility of preparing alloys with a highly dispersed structure by
hardening alloy emulsions

SOURCE: AN SSSR. Doklady, v. 160, no. 6, 1965, 1355-1357, and insert facing
p. 1333

TOPIC TAGS: alloy structure, dispersed alloy, alloy emulsion hardening, zinc alloy,
lead alloy, tin alloy, cast alloy

ABSTRACT: The authors studied the possibility of controlling the structural dis-
persion of a solid prior to its formation from an emulsion with low interphase ten-
sions. Using the Zn-Pb-Sn system as a convenient, readily melting, model (see Fig.
1) of the emulsion. Samples with 2, 4, 6, 8, 10, 12, and 14% Sn and having a combined
weight of 10 g were intensively mixed by vibration, and heated, in tightly closed,
cylindrical 10 x 20 mm steel crucibles at temperatures 50-100C higher than that of
the liquid-phase stratification region. When the temperature was reduced to a se-
lected point (T₁) within the stratification region. After maintaining the tempera-
ture for half an hour to achieve equilibrium the crucibles were cooled at a rate of

150/sec to the ambient temperature and cut along the cylinder generatrices. The metallographic sections, prepared by electrolytic etching from the halves of the discs were then examined with an MIM-8 microscope. The different structural patterns obtained in several series of experiments, by varying T₁, the concentration of the components are believed to indicate a possibility of

TITLE: The Effect of Arsenic on Properties of Rail Steel Quench-Hardened by High Frequency Current

PERIODICAL: Byul. nauchno-tekh. inform. Ukr. n.-1, in-t metallov, 1958, Nr 6, pp 90 - 103

ABSTRACT: The authors investigated "M-73" grade rail steel of the following composition (in %): C 0.67 - 0.78; Mn 0.78 - 0.97; Si 0.19 - 0.25; S 0.018 - 0.027; P 0.24 - 0.34; As 0.125 - 0.139. The steel was quench-hardened by high-frequency current (500 cycles). To investigate the effect of higher As amounts ($> 0.15\%$) experimental rails with 0.204 - 0.243% As were manufactured. It was established that an As content, increased from 0.125 to 0.24%, did not entail substantial changes in H_B , σ_b , σ_w and toughness of steel. //

serted. 1,000 copies printed.

Editorial Staff of this book: P.A. Aleksandrov, Z.S. Kazarnovskiy,
M.I. Kurmanov, M.P. Lave, V.P. Onopriyenko, V. P. Rzhovskiy, and
Ya. A. Shneyerov; Ed.: S.S. Liberman; Tech. Ed.: K.O. Durin
FOREWORD: The book is intended for the scientific personnel of
institutes and for engineers and technicians of metallurgical
enterprises and other branches of the industry.

CONTENTS: The collection of articles reviews the work carried on at
the Institute of Metals on the technology of blast furnaces, open-
hearth furnaces, and rolled stock production. It also deals
with problems of metallography, heat treatment of ferrous metals
and methods for their study. Particular attention is devoted to
the preparation of charges and blast furnace practice with increased
gas pressure, open-hearth production with oxygen blast and rolling
of light profiles. In the production with oxygen blast and rolling
accompany each article.

TITLE: ~~Favorable~~ Conditions for Induction-hardening of Various
Parts of Equipment (Ratsional'nyye rezhimy induktsionnoy
zakalki detaley oborudovaniya)

PERIODICAL: Stal', 1958, Nr 8, pp 730 - 736 (USSR)

ABSTRACT: Optimum conditions for hardening with high-frequency
currents on an installation with a rotary generator of
100 kW (2 500 cps) of rolls of various diameters, tooth
wheels, crane wheels and brake pulleys were investigated.
The results are given in tables and figures. It is con-
cluded that by using the above equipment for hardening a
depth of the active layer of 2 - 4 mm can be obtained.
The total depth of the hardened layer of up to 10 mm can
be obtained. Application of high-frequency hardening
brought about an increase in the service life of machine
parts, on the average, by 2-3 times.
There are 11 figures, 3 tables and 3 Soviet references.
